

# Amplicon sequencing

USDA ARS Microbiome Workshop  
August 29, 2017  
Adam R. Rivers

# Hello!

## The Genomics and Bioinformatics Unit

Brian Scheffler – Research leader and CSIO

Stoneville, Mississippi

[Brian.Scheffler@ars.usda.gov](mailto:Brian.Scheffler@ars.usda.gov)

Adam Rivers – SY Microbiomes and microbial genomes

Gainesville, Florida

[Adam.Rivers@ars.usda.gov](mailto:Adam.Rivers@ars.usda.gov)

Justin Vaughn – SY Crop genetics

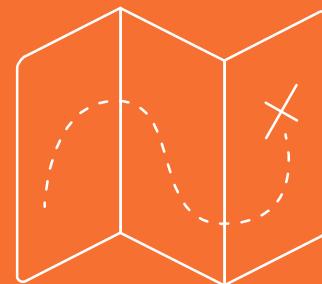

Athens, Georgia

[Justin.Vaughn@ars.usda.gov](mailto:Justin.Vaughn@ars.usda.gov)

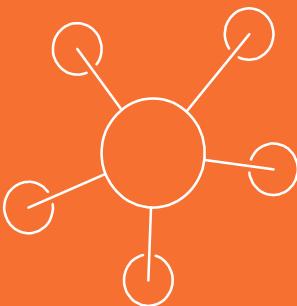

Amanda Hulse-Kemp – SY complex and polyploid Genomes

Raleigh, North Carolina

[Amanda.Hulse-Kemp@ars.usda.gov](mailto:Amanda.Hulse-Kemp@ars.usda.gov)

# Learning Objectives

- By the end of the training you should
  - 1. What amplicon sequencing is and the questions it can address
  - 2. Know how amplicon samples are processed
  - 3. Understand a standard bioinformatics workflow
  - 4. Know the types of statistical analyses that are possible with amplicon data

# 1.

What is  
amplicon  
sequencing?

# Amplicon sequencing

*“Amplicon sequencing is the amplification of a particular gene locus from a mixed group of organisms followed by the random sequencing of those targeted amplicons.”*

Which gene?

Functional

NifH  
Cox

Taxonomic

16S  
18S  
ITS

Which part?

Full length

Variable  
region

Which primer?

Designing  
good  
“universal”  
primers is  
hard.

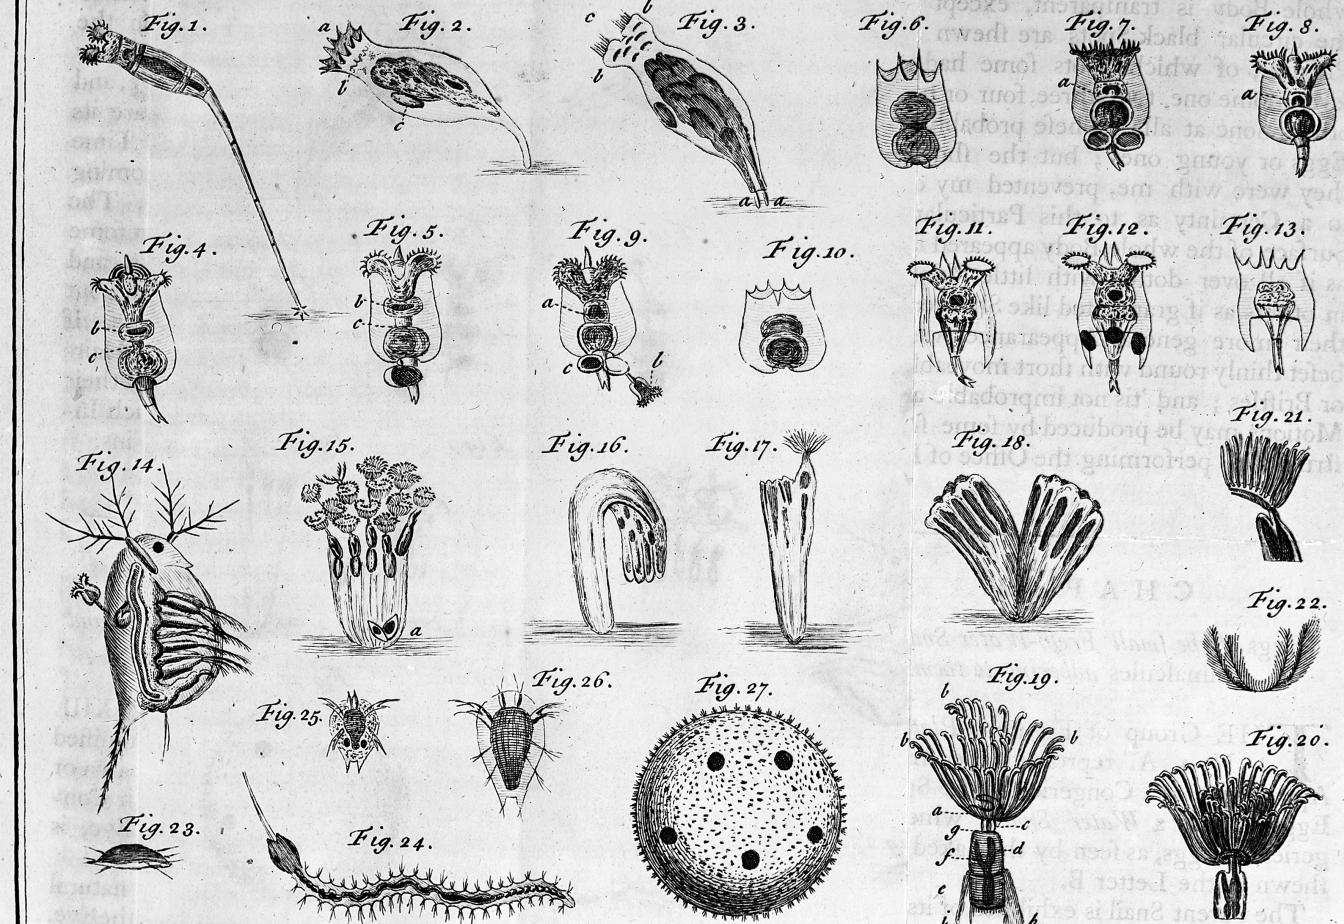

# 2.

What can  
amplicon  
sequencing  
answer?

*Composition, relative  
abundance, dynamics*

Plate XII pa. 324

## Animalcules

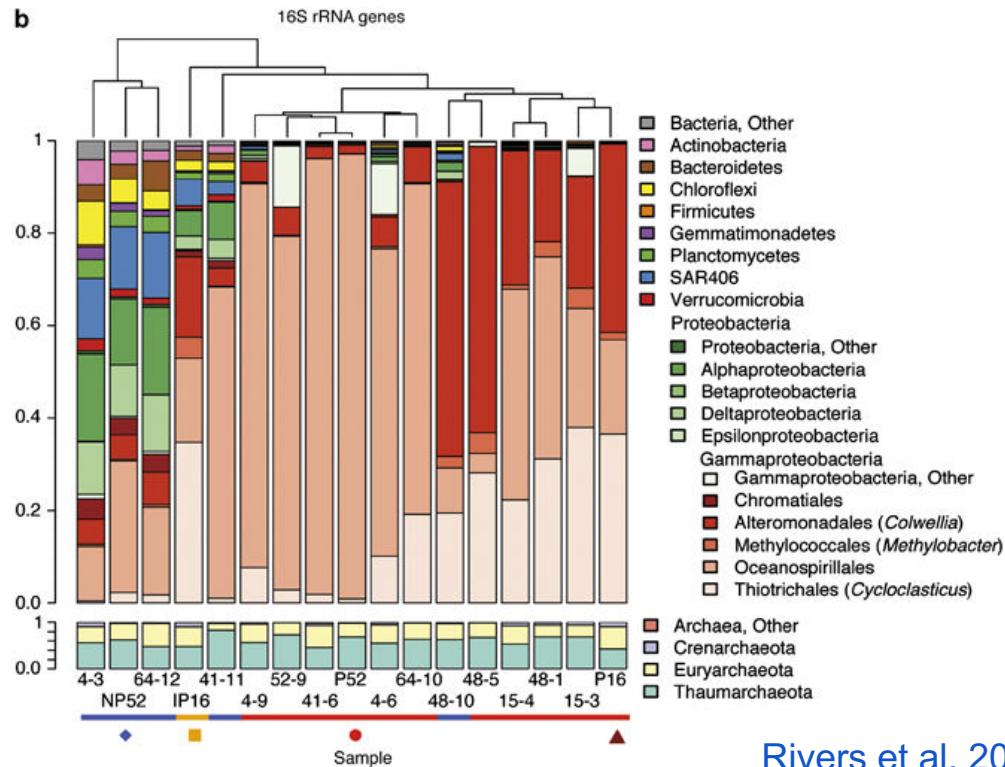

# Composition

- Resolution can be a challenge
- Different primers can't be compared
- Linking environmental data is hard

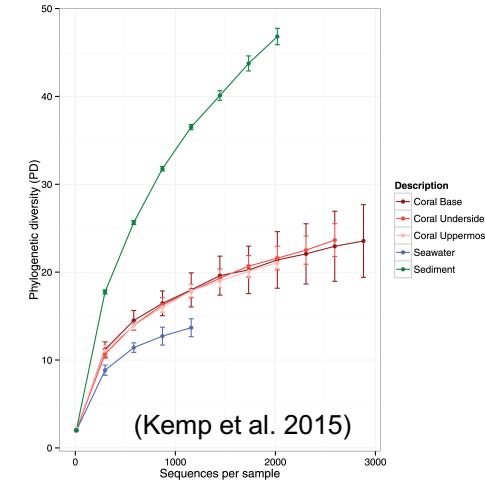

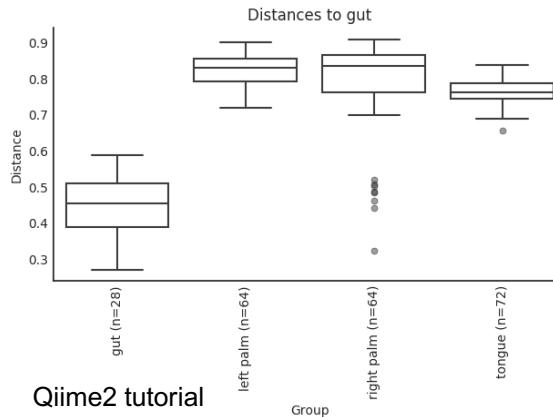

Often 16S data is used to select samples of metagenomics

At its most basic level amplicon sequencing allows for the taxonomic profiling of communities

# Diversity

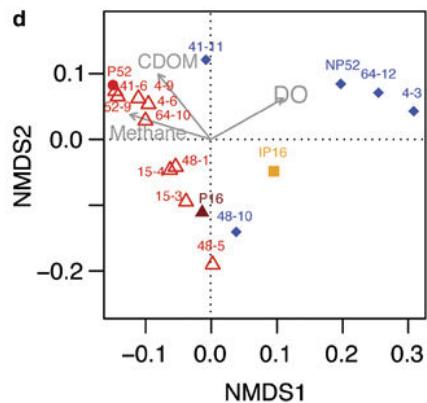

- Alpha, Beta and Gamma diversity ([R. H. Whittaker, 1972](#)) are used to describe biodiversity spatially.
- Diversity – a combination of richness and evenness
- Alpha – within community diversity
- Beta – between community diversity ([Anderson et al. 2011](#))
- Gamma – total diversity across a study area

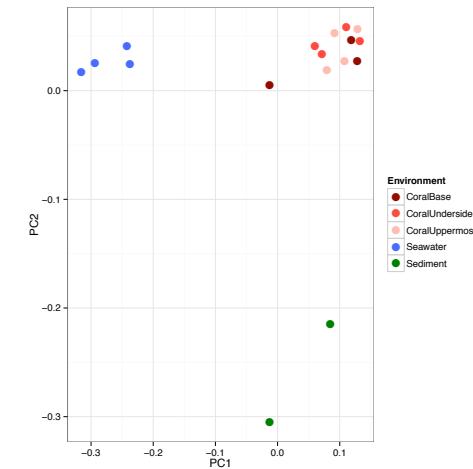

# Looking for patterns in communities

Ordination is a dimensionality reduction technique

- Start with Taxa vs sample table
- Calculate a dissimilarity matrix
- Perform ordination, e.g. NMDS, PCA, PCoA,
- Fit environmental variables

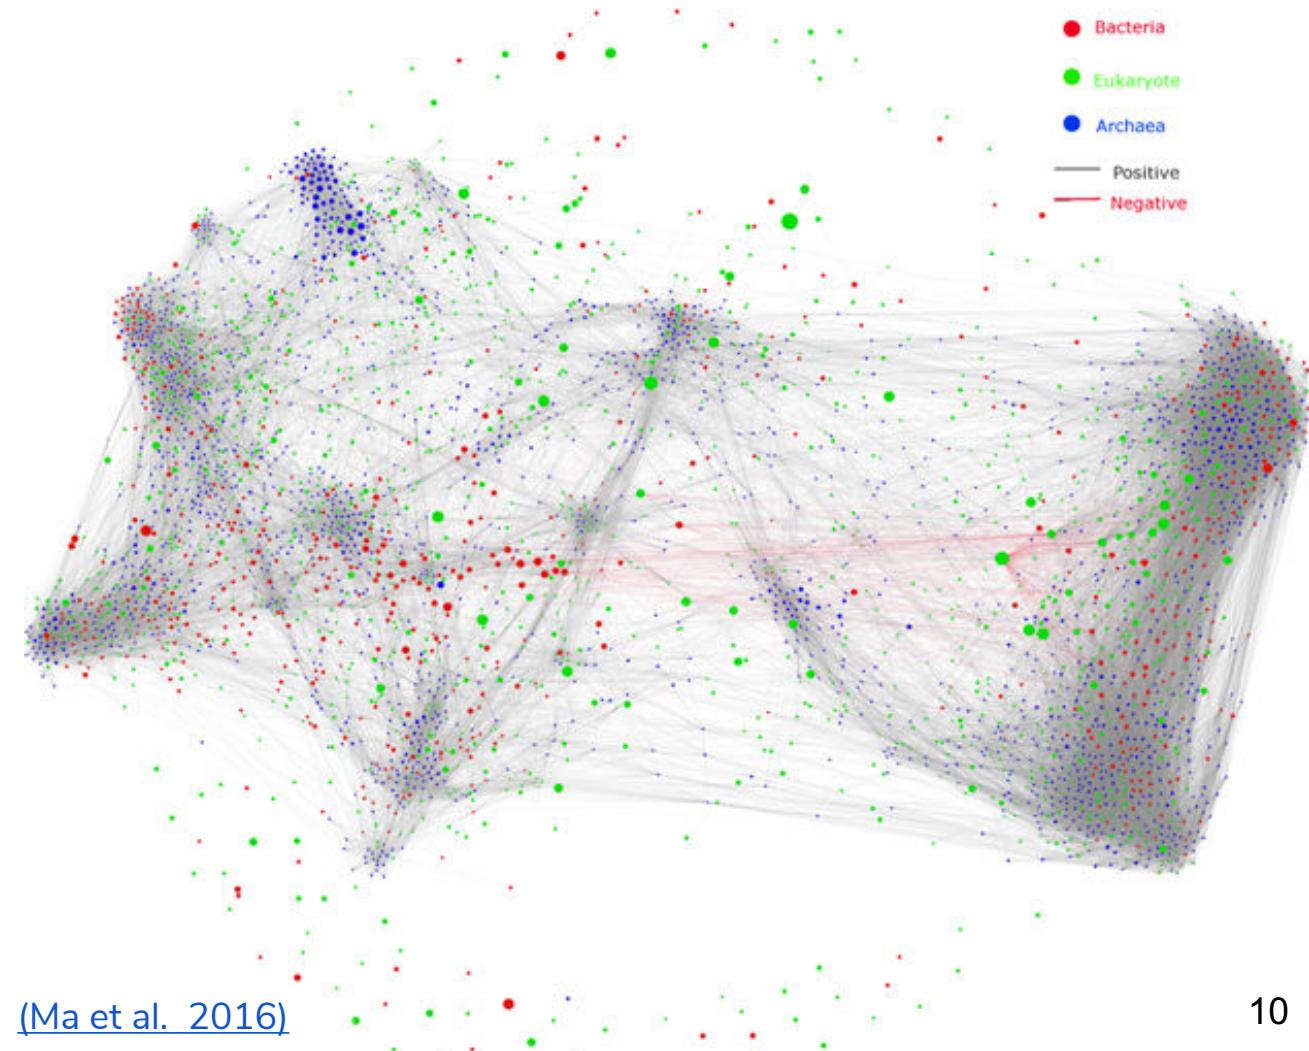

NMDS from [Rivers et al. \(2013\)](#)

PCA from [Kemp et al. \(2015\)](#)

Looking for  
co-  
occurrence

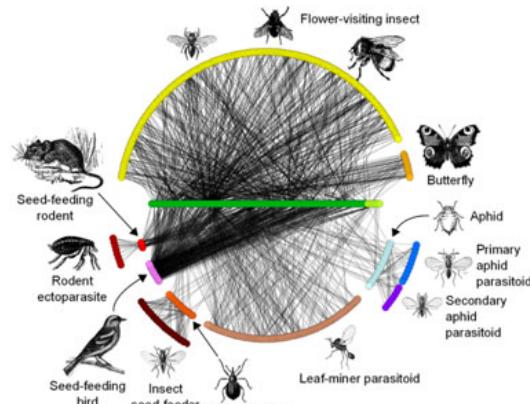

# What does co-occurrence mean?

Ideally it maps to an ecological networks

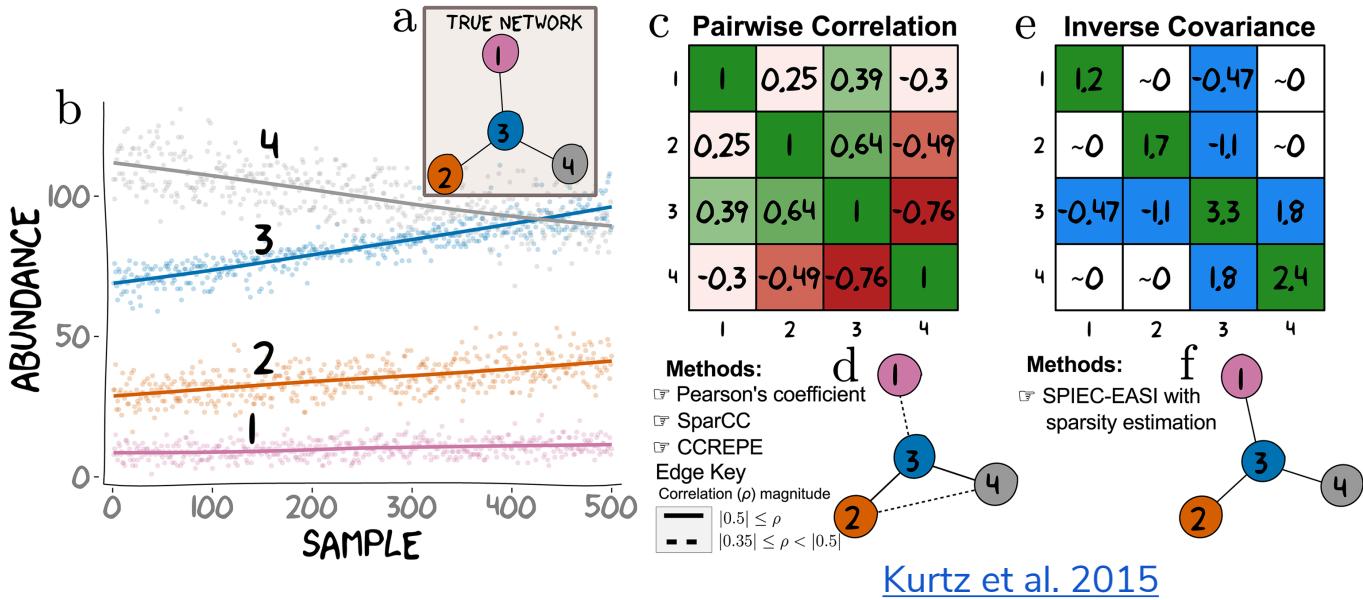

But microbial communities are different...

- Direct vs. indirect interaction
- Simplex measurements
- Vastly different sampling efforts
- Artefactual Co-variance

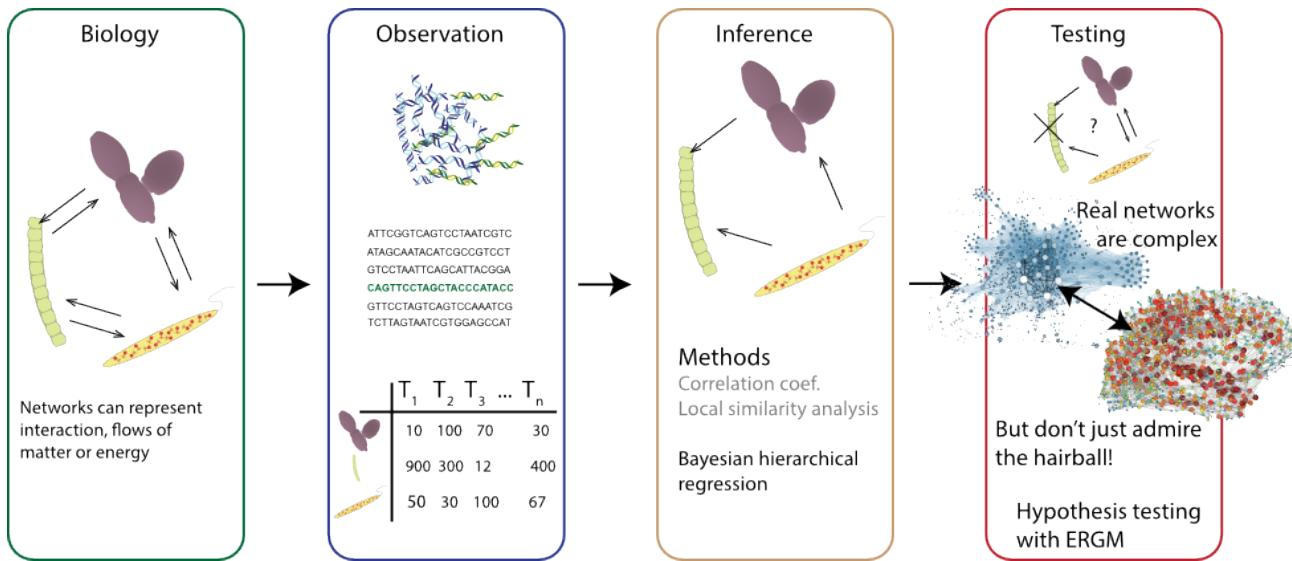

[NIMBioS](#)

# The Covariance problem

Methods to address this:  
SPIEC-EASI  
Gniess  
Bayesian network methods

# Ecological networks with predictive capability

# Types of Microbiome studies

Waste Not, Want Not: Why Rarefying Microbiome Data Is Inadmissible

Paul J. McMurdie, Susan Holmes\*

Statistics Department, Stanford University, Stanford, California, United States of America

Normalization and microbial differential abundance strategies depend upon data characteristics

Sophie Weiss<sup>1</sup>, Zhenjiang Zech Xu<sup>2</sup>, Shyamal Peddada<sup>3</sup>, Amnon Amir<sup>2</sup>, Kyle Bittinger<sup>4</sup>, Antonio Gonzalez<sup>2</sup>, Catherine Lozupone<sup>5</sup>, Jesse R. Zaneveld<sup>6</sup>, Yoshiki Vázquez-Baeza<sup>7</sup>, Amanda Birmingham<sup>8</sup>, Embrette R. Hyde<sup>2</sup> and Rob Knight<sup>2,7,9\*</sup>

Rarefaction subsamples without replacement reads from each sample often to the of the smallest library in an experiment sometimes 10-100x.

Alternatively data can be scaled using a normalization method like the Trimmed Mean of Means transformation and modeled using a negative binomial model.

# 3.

## Field to sequencer – the nuts and bolts.

*Sample preparation  
and sequencing*

# Collect DNA

Amplicon DNA sampling is much more forgiving than RNA sampling.

4°C Short-term  
-20°C Long-term  
[\(Rubin et al. 2013\)](#)

Collect and store  
within 1-2 hours

Consider collecting RNA and storing it in RNAlater  
(Saturated Ammonium Sulfate) at 4°C to sequence the  
active fraction.

# Collect Metadata

“There is no such thing as metadata,  
everything is data.”  
- Susan Holmes

- Sample collection is the time to record environmental data
- The GSC has created environmental and sequence data standards, [MIxS](#). Use them as a guide for your collections.
- Store environmental data in NCBI or ENA Biosamples databases or Gold database. Do it now, while you still remember what you did. You can link sequence data later.

# DNA extraction

Amplicon sequencing is more forgiving than metagenome sequencing.

## **Target amount of DNA for sequencing:**

**50-100ng at 3-50 ng/ul in 10-50 ul**

About 10ng is needed, but who wants to have just the bare minimum of Flair-DNA?

## **Quality:**

Length is less important than amplification.

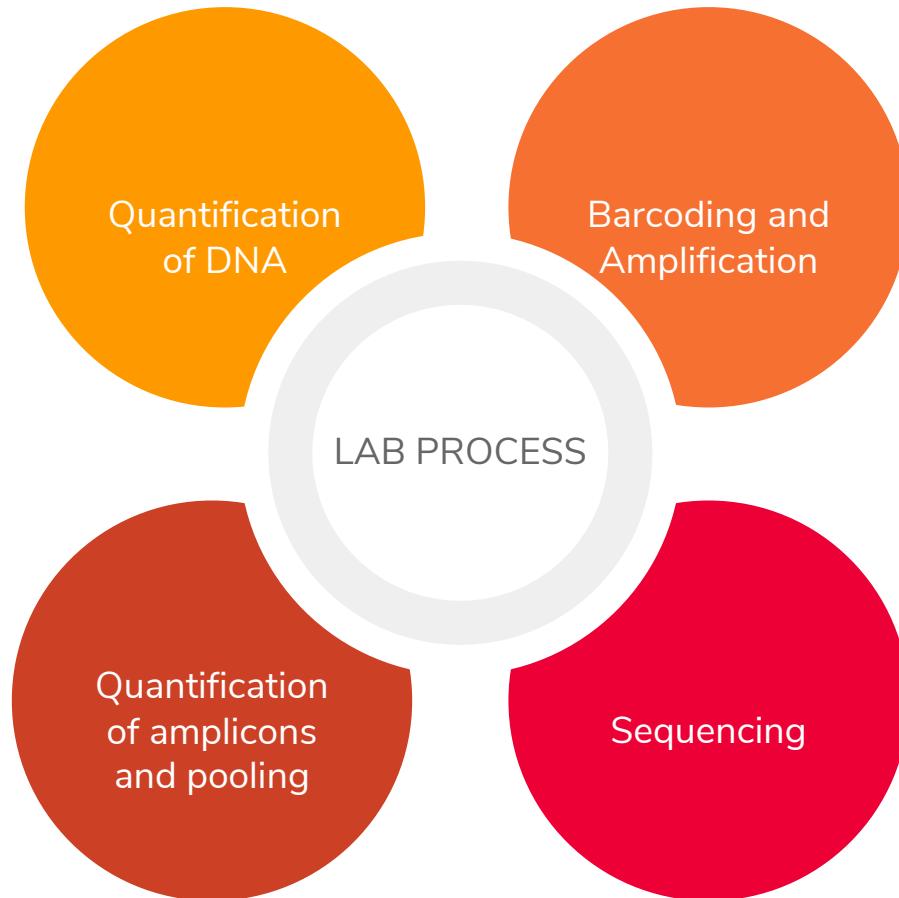

PCR test with universal part of sequencing primers.

PCR inhibitors like humic acids can be most disruptive.

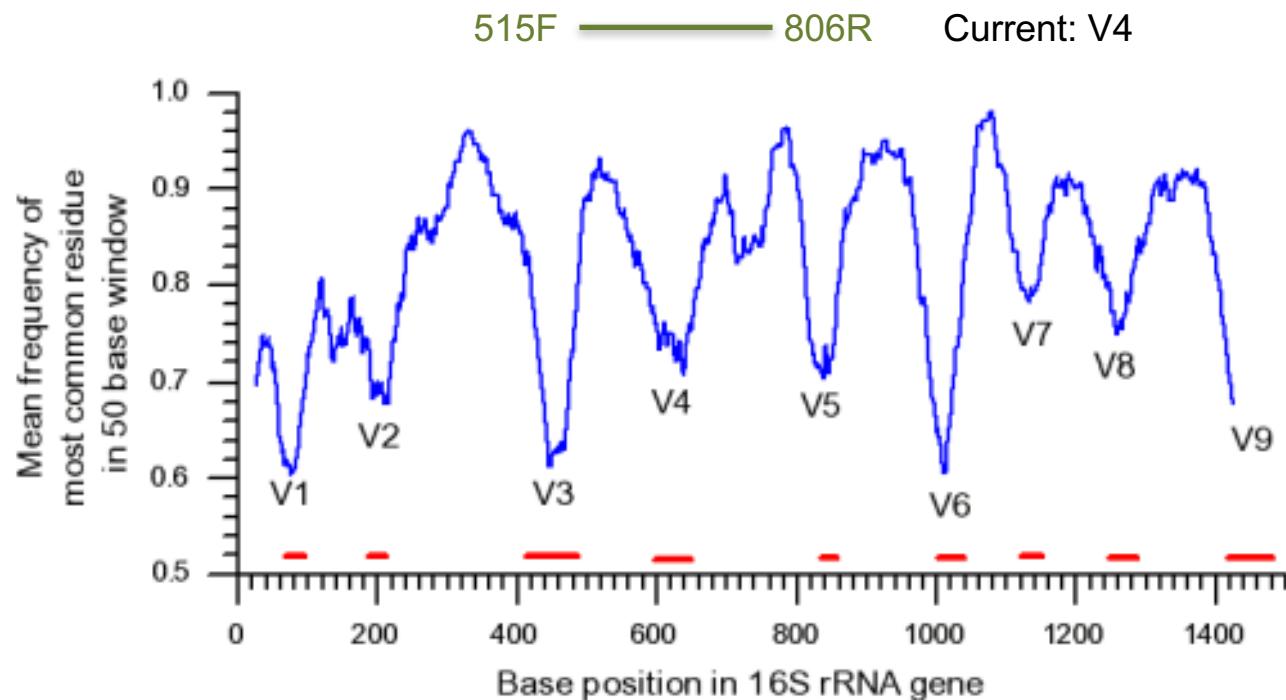

## **Internal standards:**

For quantitative work control DNA is sometimes added during extraction ([Moran et al. 2013](#)).

# Barcoding

# Sequencing

2 96 well plates

PCR with 16 forward primer  
24 distinct reverse indexes

- 2x300bp Paired Reads
- 44-50M reads
- ~360,000 tags per sample
- 36 hours

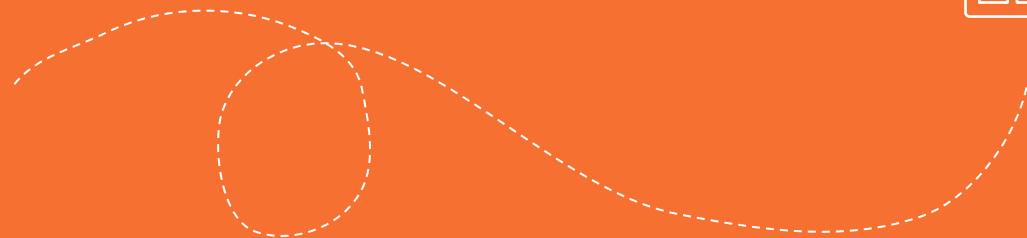

illumina®  
MiSeq

# 4.

## Analysis of amplicon data

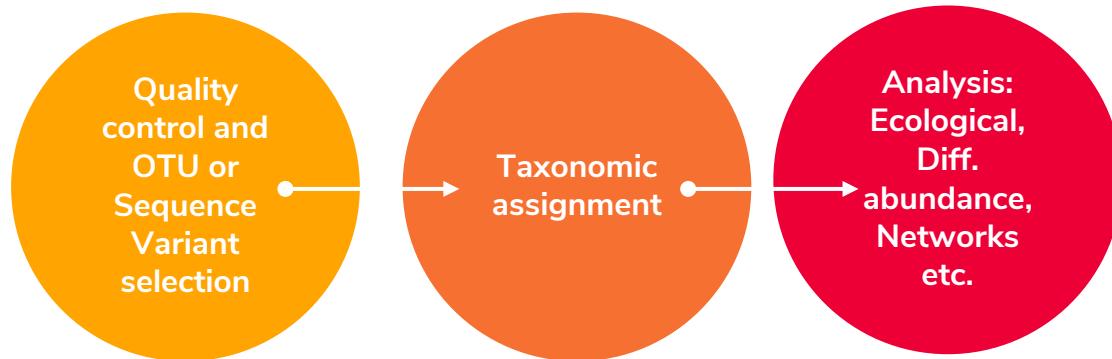

*What to do with all  
those fastq.gz files.*

GATC  
CATC  
CCGA

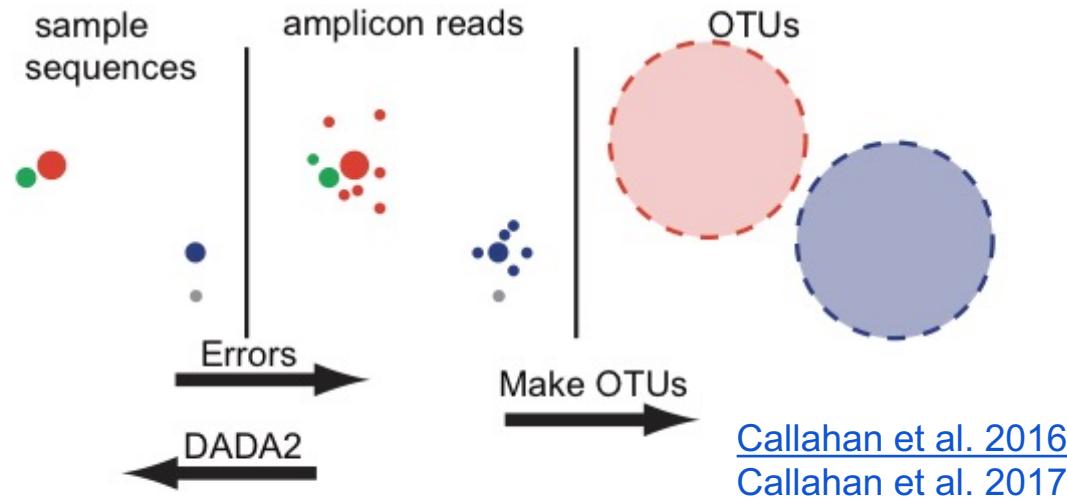

# Amplicon sequencing

Amplicon analysis follows a basic workflow with many possibilities for custom analysis

# Why OTU's were used and why Sequence variants are replacing them.

The field is moving this way:

Dada2 - [Callahan et al. 2016](#) (Holmes Lab)

Denoise - [Amir et al. 2017](#) (Knight Lab)

Unoise2 – [Edgar 2016](#)

# Taxonomic assignment

## Databases

| Database                         | Description  | License   |
|----------------------------------|--|---|
| <a href="#">Greengenes</a>       | A curated database of archaea and bacteria - static since 2013                             | <a href="#">CC BY-SA 3.0</a>                            |
| <a href="#">Silva</a>            | The most up-to-date and extensive database of prokaryotes and eukaryotes, several versions | <a href="#">Free academic / Paid commercial license</a> |
| <a href="#">The RDP database</a> | A large collection of archaeal bacterial and fungal sequences                              | <a href="#">CC BY-SA 3.0</a>                            |
| <a href="#">UNITE</a>            | The primary database for fungal ITS and 28S data   | Not stated  |

## Classifiers

RDP [Classifier](#) – The go-to NB classifier for most people

[Sintax](#) – Edgar's short Kmer classifier

Qiime2's - NB classifier based on Scikit learn

# Analysis

The range of analysis preformed after 16S is wide:

- Taxonomic profiling
- Differential abundance analysis
- Diversity measurement
- Network analysis
- Hypothesis testing
- Identifying responsive SV's
- Correlating taxa with environmental conditions
- Understanding how related taxa are.

Is best to jump in and try these  
yourself in the [Amplicon Tutorial](#)
